What to expect

- A high-level introduction to agentic LLM systems
- Hands-on tutorials for getting started with some important frameworks
- at 5:30pm, you should be able to talk to your own PDFs

What not to expect

- An introduction to LLMs
- Theory
- An overview of research about agentic systems

Overview

- Introduction to **agentic systems**
- **hands-on:** GitHub Repo, API Keys, getting set up
- Introduction to **LangGraph**
- **Code-along:** Building a RAG chatbot
- Introduction to **MCP**
- **Live-Coding:** Building an MCP Server
- Introduction to **Orchestration of Agents**
- **Demo:** Building a deep research assistant
- coffee break
- **build-your-own:** audience creates agents for their ideas
- time permitting: showcasing some examples from the audience

What are agents?

Tübingen AI Center

Remember the early days of ChatGPT?

ChatGPT could answer complicated questions about all sorts of topics, write poems, ... but

- questions about current events were answered completely wrong
 - because they were not included in the training data
- No reasoning
 - it could not reason about how to proceed with solving a problem
- No handling of PDF files and images
 - only text input was allowed
- no image generation
- no personalization
 - it didn't remember anything from past conversations

Making LLMs more powerful

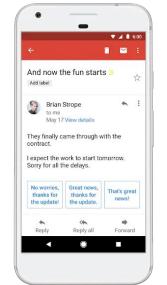

- make LLMs call tools
 - ReAct
 - ToolFormer
 - ViperGPT
- give models access to data (Retrieval augmented generation)
 - REALM
 - DPR
 - RETRO
 - InstructRetro

LLMs using tools

- ReAct (2022): tool usage via few-shot prompts and reasoning
- ToolFormer (2023):
-
- Retrieval augmented generation: Give models access to additional databases for better responses

Agent or not?

What is:

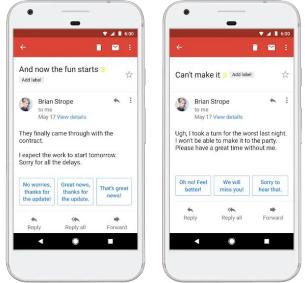

What is an agent?

- A system that independently accomplishes tasks on your behalf
 - It **leverages an LLM** to **manage workflow execution** and **make decisions**. It recognizes when a workflow is complete and can proactively correct its actions if needed. In case of failure, it can halt execution and transfer control back to the user.
 - It has access to various **tools** to interact with external systems—both to **gather context** and to **take actions**—and dynamically selects the appropriate tools depending on the workflow's current state, always operating within clearly defined guardrails.
- you know it's an agent when you see it
- Agency is a spectrum, it's not binary

~ OpenAI, a practical guide to building agents

Agent or not?

Google

Copilot Agent

Thanks! I tried the static map, but it fails:

M Makefile:8

I see the issue. The GeoJSON file structure has different column names than what the script is expecting. Let's examine the actual structure of your GeoJSON file and fix the `* static_map_generator.py` script accordingly.

✓ `head -20 9nt8-h7nd.geojson | grep -v "geometry"`

Let's try a different approach to inspect the GeoJSON file:

✓ `python3 -c "import geopandas as gpd; df = gpd.read_file('9nt8-h7nd.geojson'); print(df.columns.tolist()); print(df.head(1).to_dict('records')[0].keys())"`

Now I understand the issue! The GeoJSON file uses `boroname` instead of `boro_name`. Let's fix the `* static_map_generator.py` script:

✓ Read `* static_map_generator.py`, lines 58 to 68

✗ `* static_map_generator.py +9 -4`

Now let's also check if there might be other column name issues in the script:

> Searched text for `ntaname` (**/*static_map_generator.py), 20 results

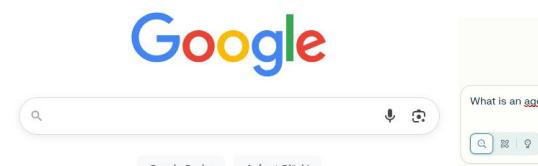

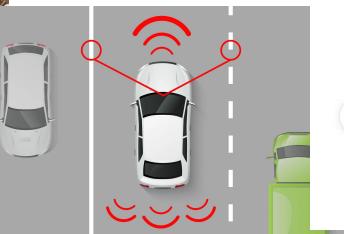

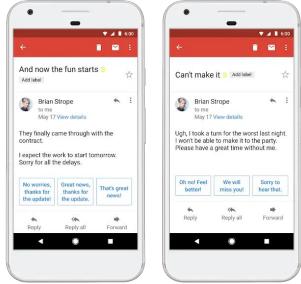

Great! The column name `* ntaname` exists in both the script and the actual GeoJSON file, so no more changes are needed for those references.

Agents are not a new thing

- ChatGPT transformed into an agent over time
 - Launched (Nov 2022)
 - Calling Wolfram Alpha (Apr 2023)
 - Bing & Webbrowsing (Mid 2023)
 - Memory (2024)
 - Deep Research (April 2025)
 - ChatGPT Agent (July 2025)

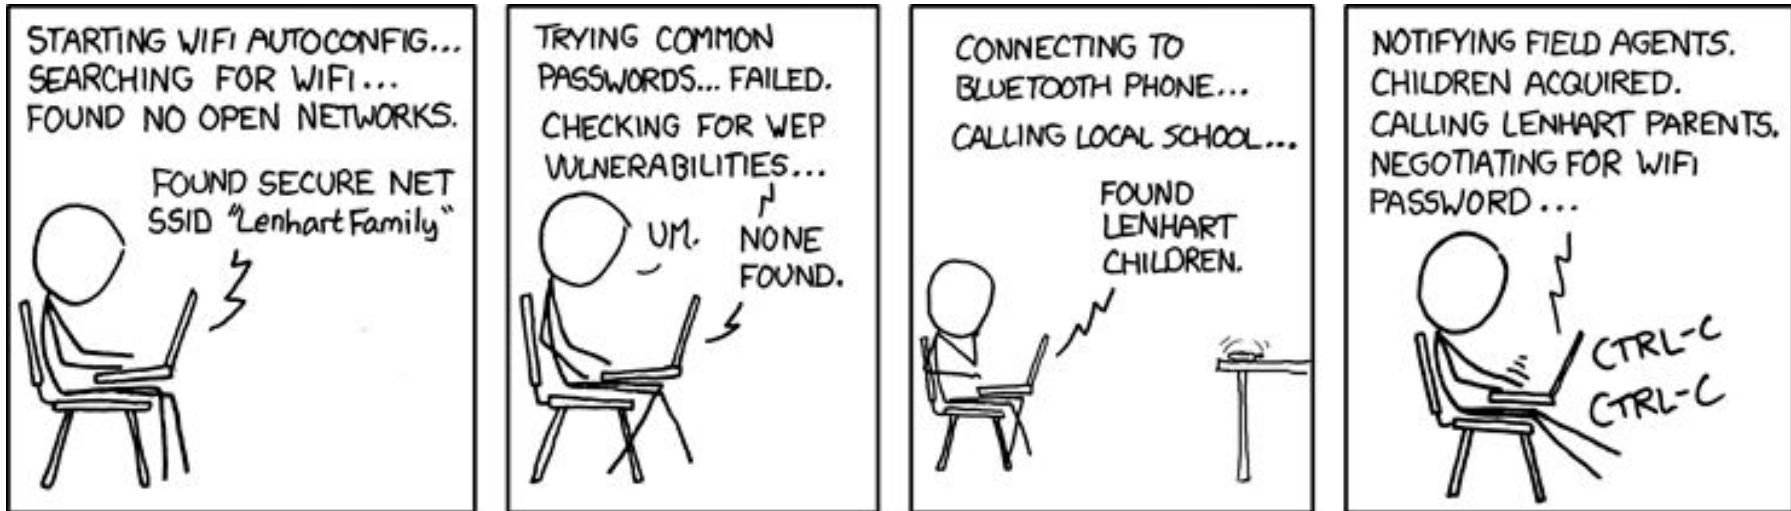

Agent or not?

perplexity

What is an [agentic](#) system?

Agentic Concepts

- tools: function calling
- has access to resources
- has prompts(?)

Examples

- Deep Research/ari (you.com)
- Perplexity
- Devin
- Claude Code/Codex
- Cursor/Copilot/replit
- jules(google)
- Wiso/Law firms/
- ChatGPT in general these days
- [manus.im](#)
- Google astra
- figma/loveable (originally GPT engineer)
- NotebookLM

 NotebookLM

Examples

Chatbot
Claude Desktop, ChatGPT, ...

Organizer
NotebookLM, Paperless-AI

(Coding) Agent
Aider, Gemini CLI, Claude Code, ...

IDE
VS-Code, Cursor, Windsurf, ...

Building agents with LangGraph

Tübingen AI Center

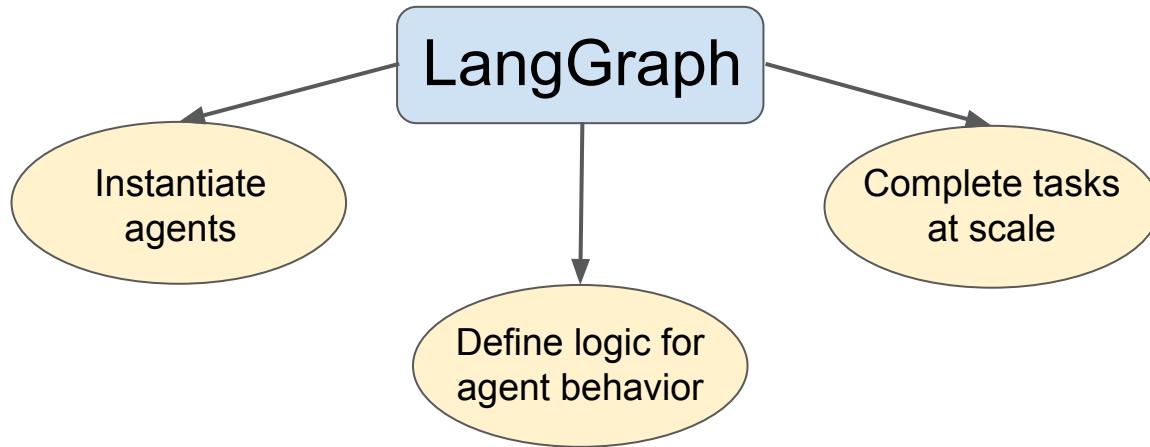

MINERVA

What is LangGraph?

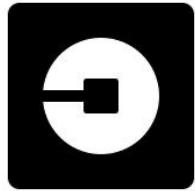

- LangGraph is an *agent orchestration framework* developed by **LangChain**, a company that creates frameworks and tools for agent-driven systems.

Heard of LangGraph already?

- Internally uses “SQL-Bot” to write SQL from natural language.
- “SQL-Bot” is a multi-agent system made with LangGraph

- Uses LangGraph to make a network of agents for internal use.
- Automates code migration & unit-test generation

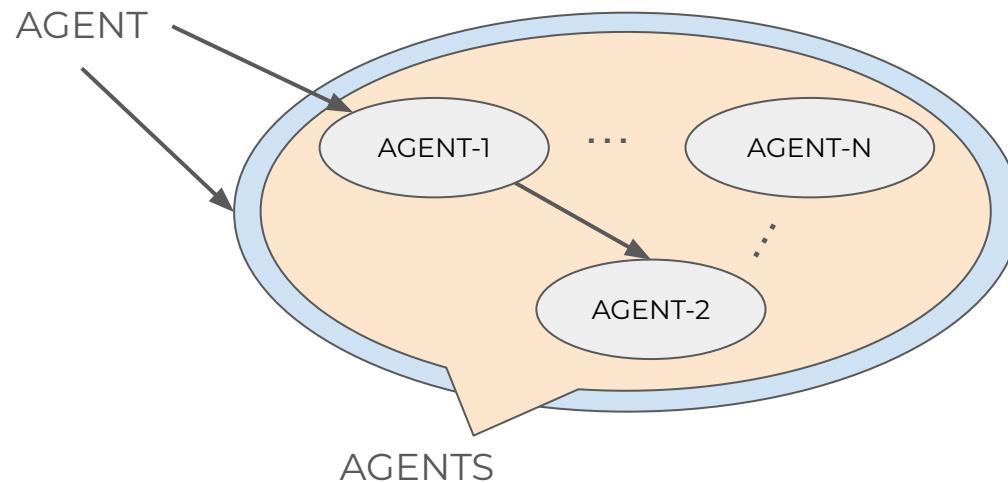

- LangGraph-based AI assistant handles custom support tasks.
- Scales for as large as 85M active users & reduces resolution time by 80%.

Clarifying terminology: Agent v/s Agents

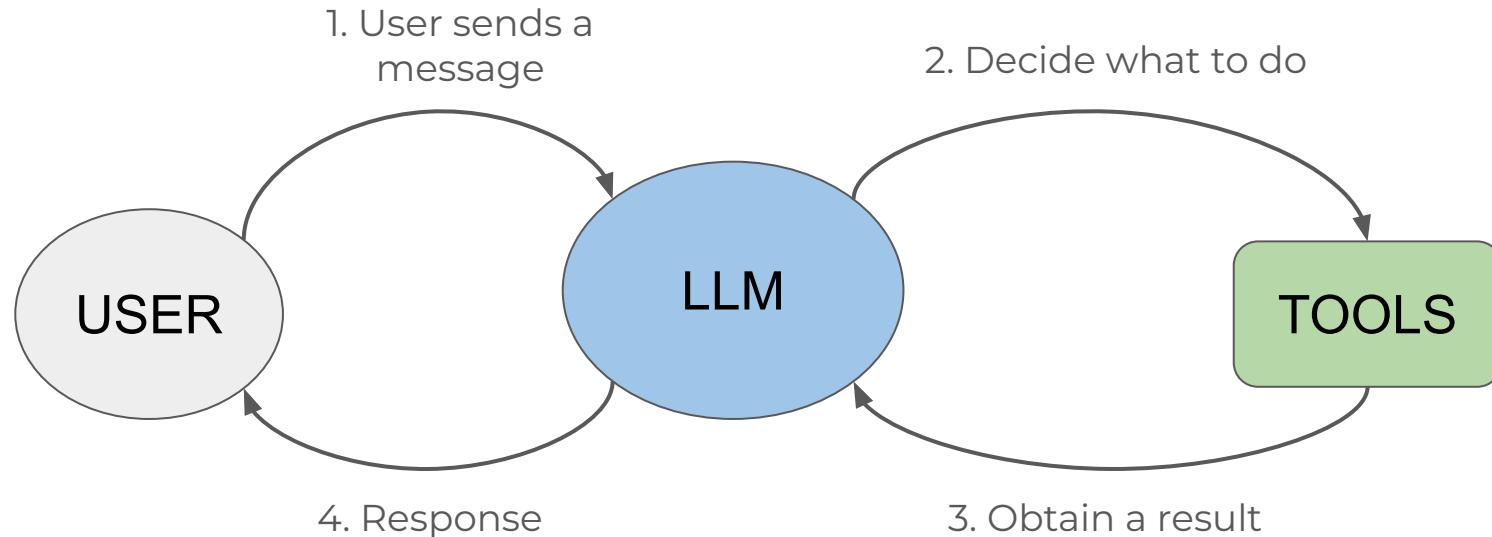

- Our system, that autonomously performs tasks for us **is an agent**.
- A component of the system that also autonomously performs tasks **is also an agent**
 - just at a different hierarchical level
- **Agents** (plural): 2 or more instances of **agent** at the same hierarchical level.

Yes

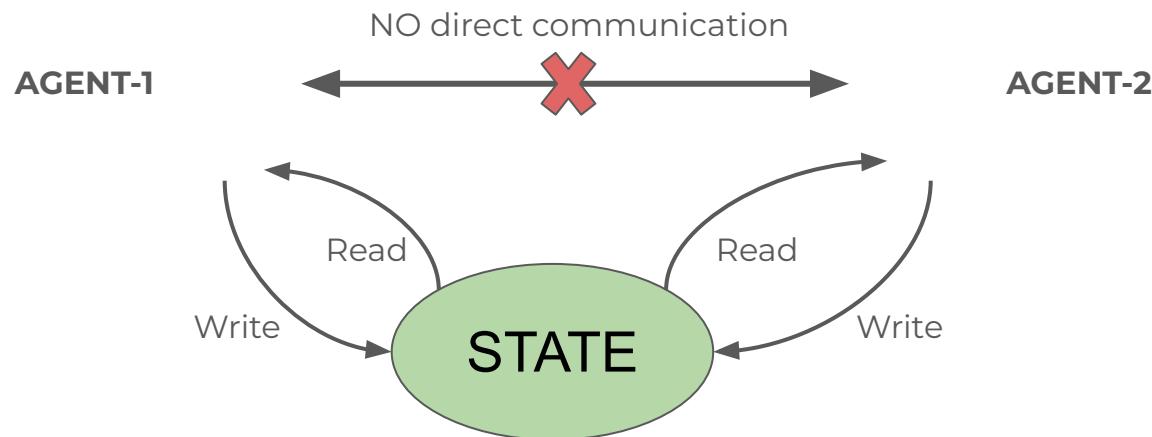

High-level abstraction: basic LangGraph system

Basic components: State

- **State:**
 - Typed-Dict all nodes operate on.
 - Node-to-node communication happens by reading and writing to the state.

Basic components: Nodes & Edges

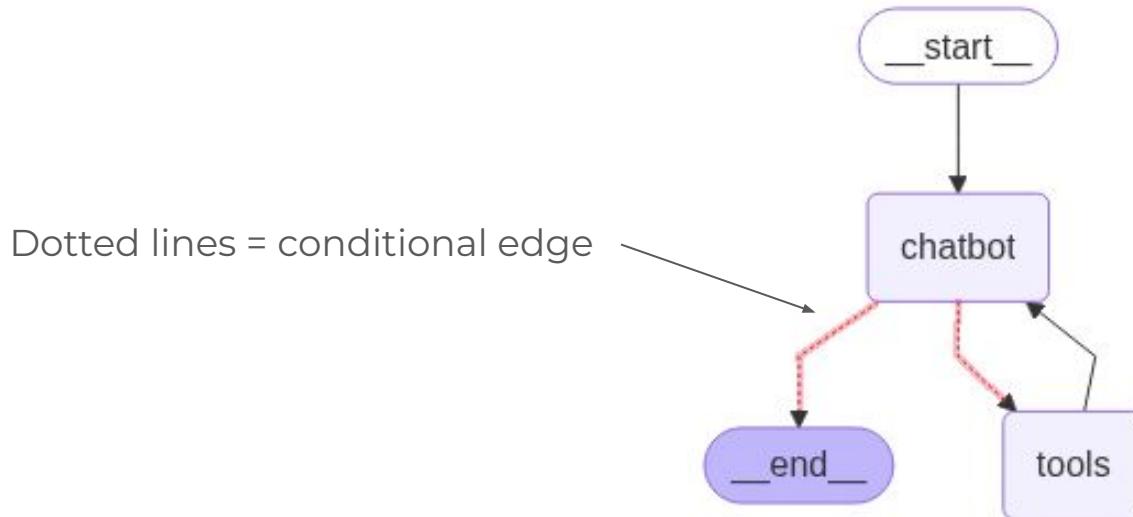

- **Nodes:**
 - Are basically functions (**input**: current state+config, **output**: update to state)
 - Usually will make use of calling an LLM (with some prompt).

- **Edges:**
 - Specify how the agent should transition between nodes.
 - used as `graph.add_edge(start_node, end_node)`

Conditional Edge

- Used when we want to transit between nodes based on certain conditions.
- Implemented via: `graph.add_conditional_edge("node", routing_function)`
- 2nd argument (`routing_function`) specifies the conditional routing from "node".

We need to compile our graph!

- **StateGraph**
 - ONLY the graph that we model our system with.
- **CompiledStateGraph**
 - We can't "run" anything with an un-compiled **StateGraph**
 - Compiling the graph lets us send inputs and get outputs, using **invoke()** and **stream()**

invoke()

Run the graph (get an output) given an input and a config.

stream()

Display each step of the graph's execution given a single input.

Tools

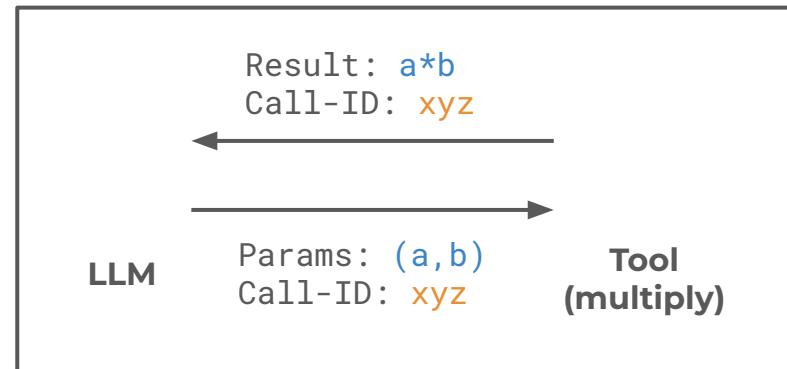

- Wraps a function & its input schema to pass it to an LLM tuned to use tools.
- LLM requests the execution of the function by passing the input parameters.
- Each tool call has an ID given with the input by the LLM.
- Tool calls terminate after the state receives a matching ToolMessage.

```
from langchain_core.tools import tool

@tool("multiply_tool", parse_docstring=True)
def multiply(a: int, b: int) -> int:
    """Multiply two numbers.

Args:
    a: First operand
    b: Second operand
    ...
    return a * b
```

ToolNode

- Like a prebuilt “toolbox” in LangGraph

```
tools_by_name = {tool.name: tool for tool in tools}
def tool_node(state: dict):
    result = []
    for tool_call in state["messages"][-1].tool_calls:
        tool = tools_by_name[tool_call["name"]]
        observation = tool.invoke(tool_call["args"])
        result.append(ToolMessage(content=observation, tool_call_id=tool_call["id"]))
    return {"messages": result}
```

Messages in LangGraph

- **BaseMessage:** abstract class for all kinds of messages
- **HumanMessage:** messages from humans (users)
- **AIMessage:** messages from LLMs
- **ToolMessage:** messages from tools
- **SystemMessage:** messages from the system (eg: system prompts, etc)

Handling the State - *reducer functions*

- Specifies how existing state (first positional argument) and update (second positional argument) should reduce to a new state.
- Otherwise the state key will be overwritten!

```
def add(left, right):
    """Can also import `add` from the `operator` built-in."""
    return left + right

class State(TypedDict):
    messages: Annotated[list[AnyMessage], add]
    extra_field: int
```

Examples: Run them with us!

- Scan QR code → README/Quickstart → open `01_basic_langgraph_chatbot.ipynb`
- You should be able to run the code & replicate the example → set up done

Github: <https://github.com/TuebingenAI.Center/agent-tutorial>

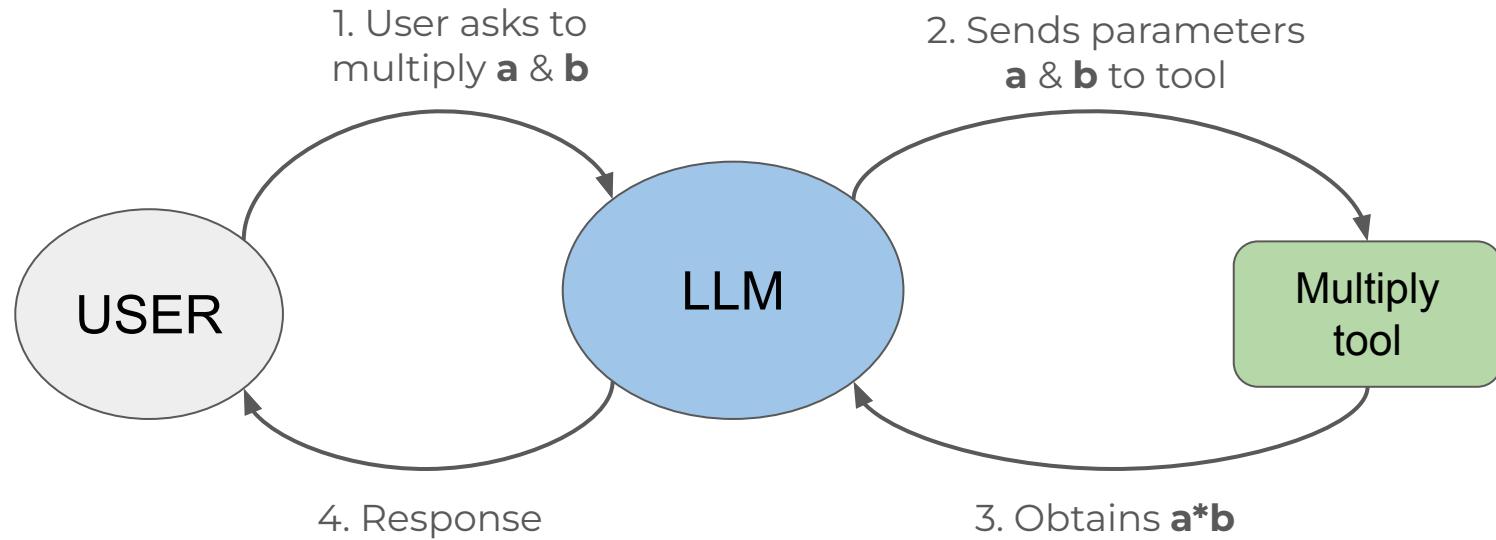

API Keys: <https://shorturl.at/X11q3>

Let's look at a simple example

Example 1: multiply two numbers

Could just as easily be another tool, e.g. web search, code editor, email, etc.

Questions so far?

Handling the State - *updating the state*

- Updates through returning from a node

```
def node(state: State):
    messages = state["messages"]
    new_message = AIMessage("Hello!")

    return {"messages": messages + [new_message], "extra_field": 10}
```

- Updates (+ Routing) from within a node/tool

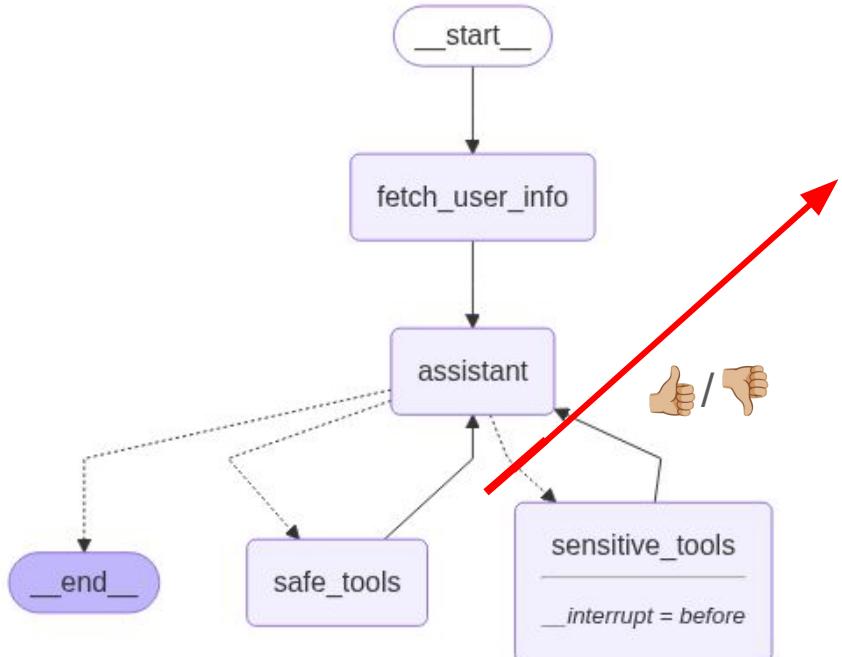

```
def my_node(state: State) -> Command[Literal["my_other_node"]]:
    if state["foo"] == "bar":
        return Command(update={"foo": "baz"}, goto="my_other_node")
```

- Updates on a compiled graph from outside

```
graph.update_state(config, {"name": "LangGraph (library)"})

graph.invoke({"user_input": "My"})
```

Interruptions/Human in the Loop

If execution is interrupted: state stores where its supposed to go next in its **.next** attribute

```
snapshot = graph.get_state(config)  
snapshot.next[0] # "name_of_node"
```

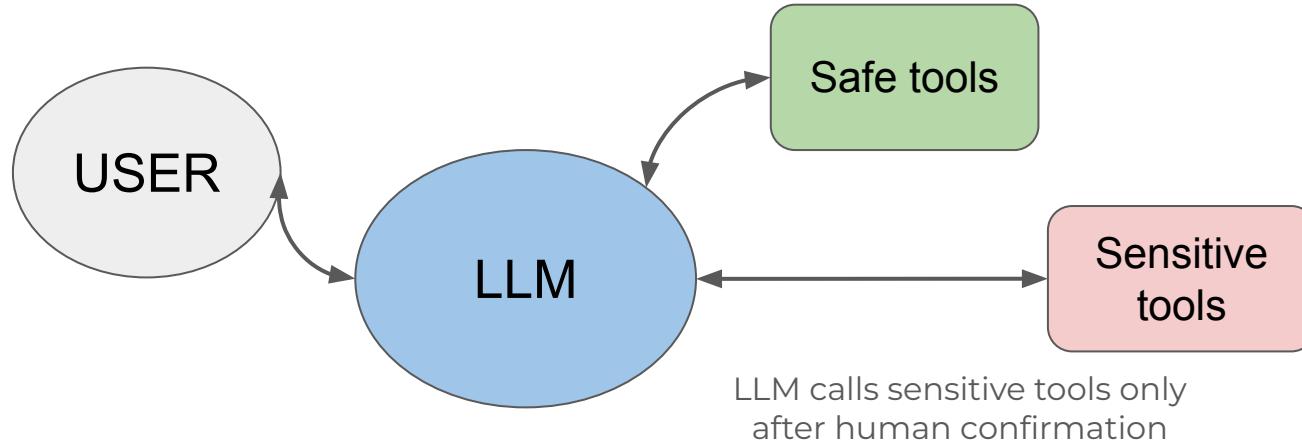

Let's look at another example

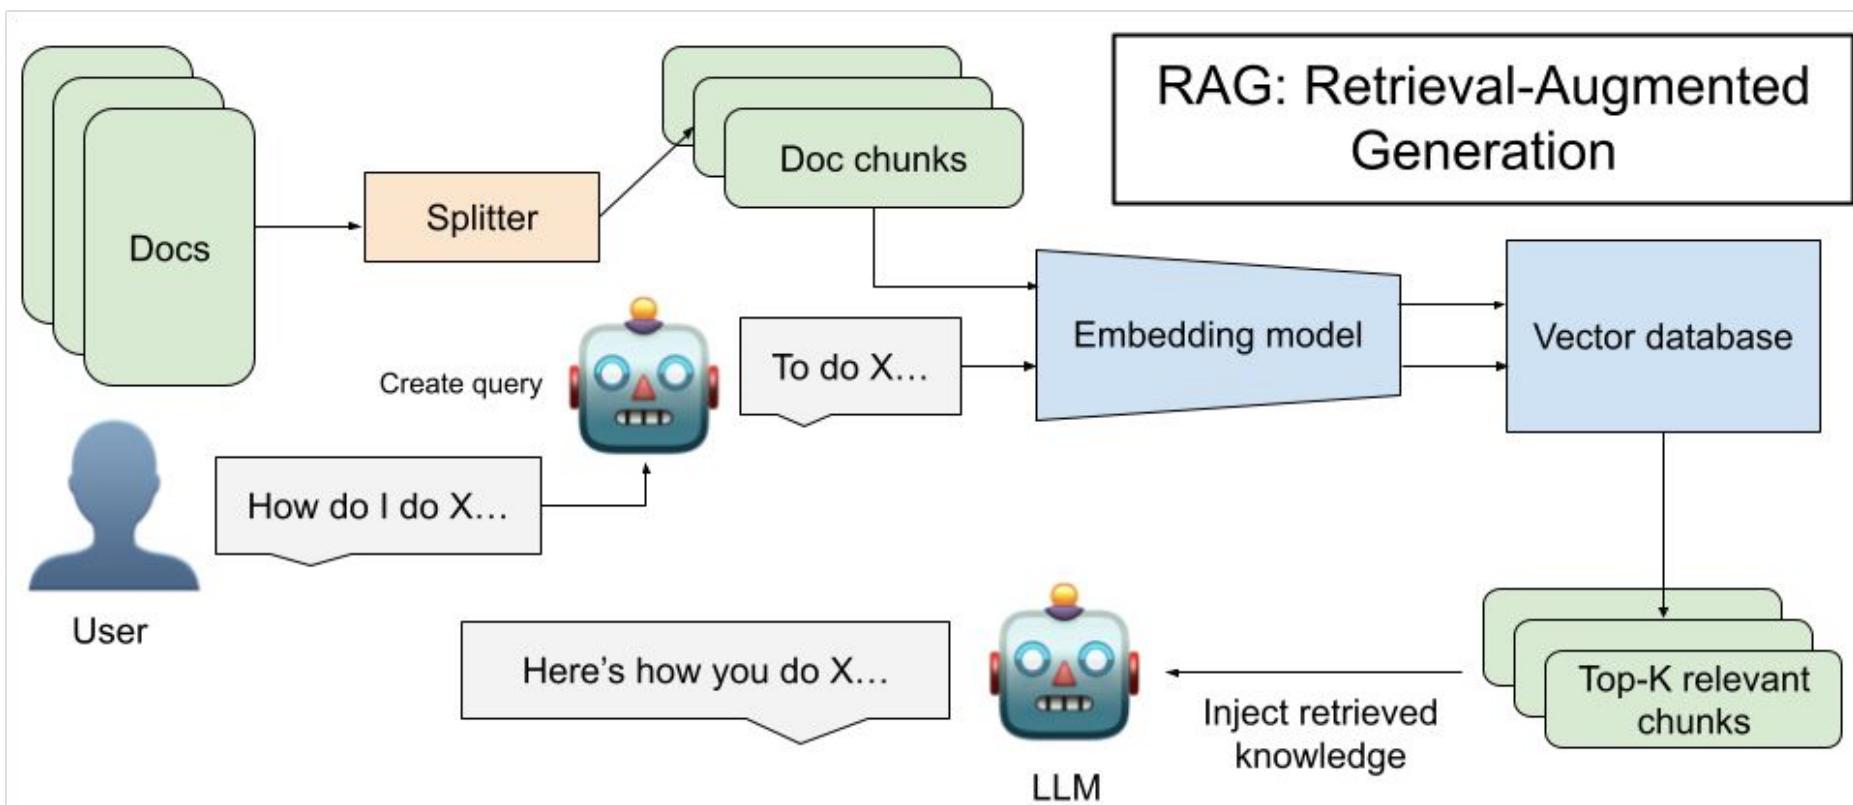

Example 2: Chat with PDF / YouTube video

- A system that uses **RAG** to inject relevant knowledge from PDFs and YouTube transcripts into the LLM context. Allows users to chat about specific topics reliably
- **Key lesson:** interrupting execution to put humans-in-the-loop

Example 2: what is RAG?

Questions so far?

Model Context Protocol (MCP)

The USB-C of AI Applications

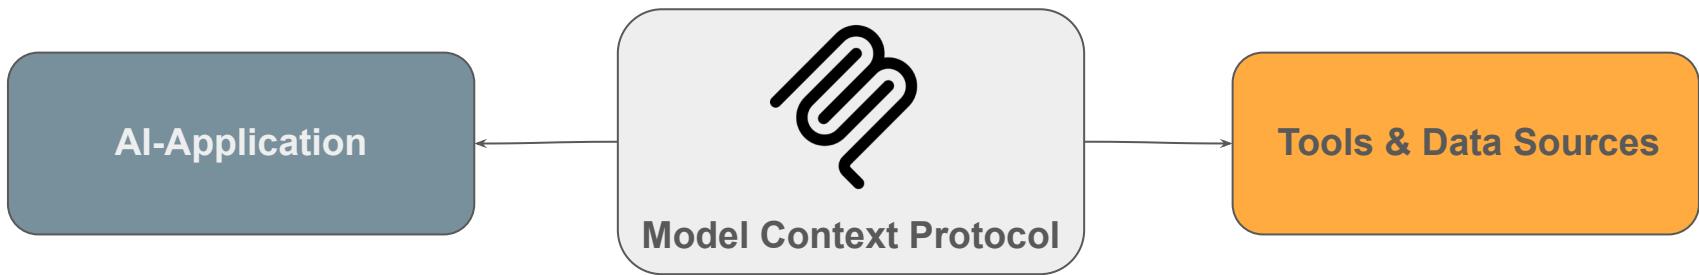

- No new revolutionary tool/idea/innovation
- Standardization of ideas and patterns that came before:
Tool Calling, RAG, Prompt Engineering, ...

“Think of MCP like a USB-C port for AI applications”

modelcontextprotocol.io

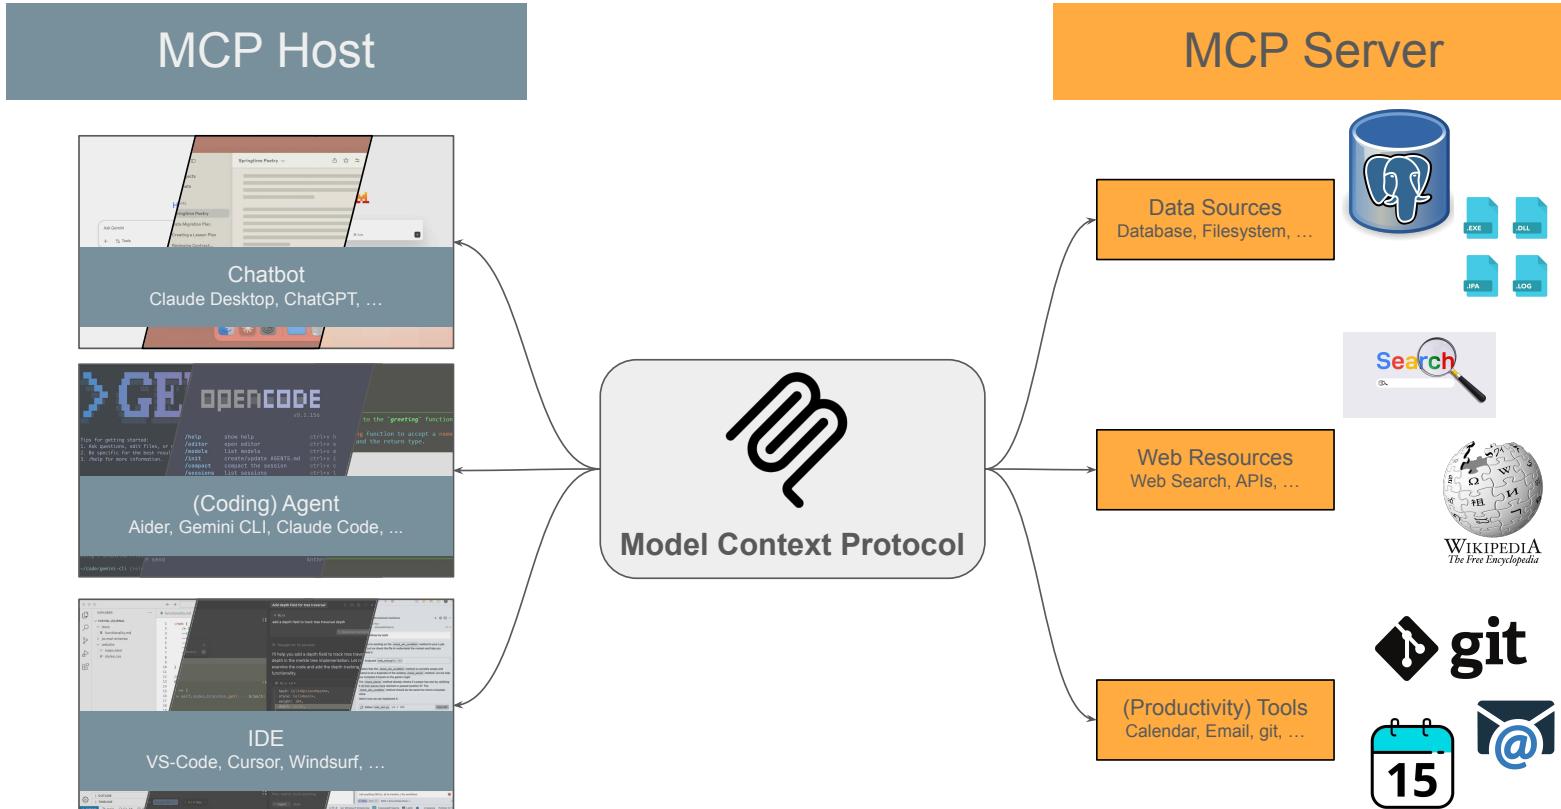

The real value lies in standardization, not innovation

MCP as Communication Protocol

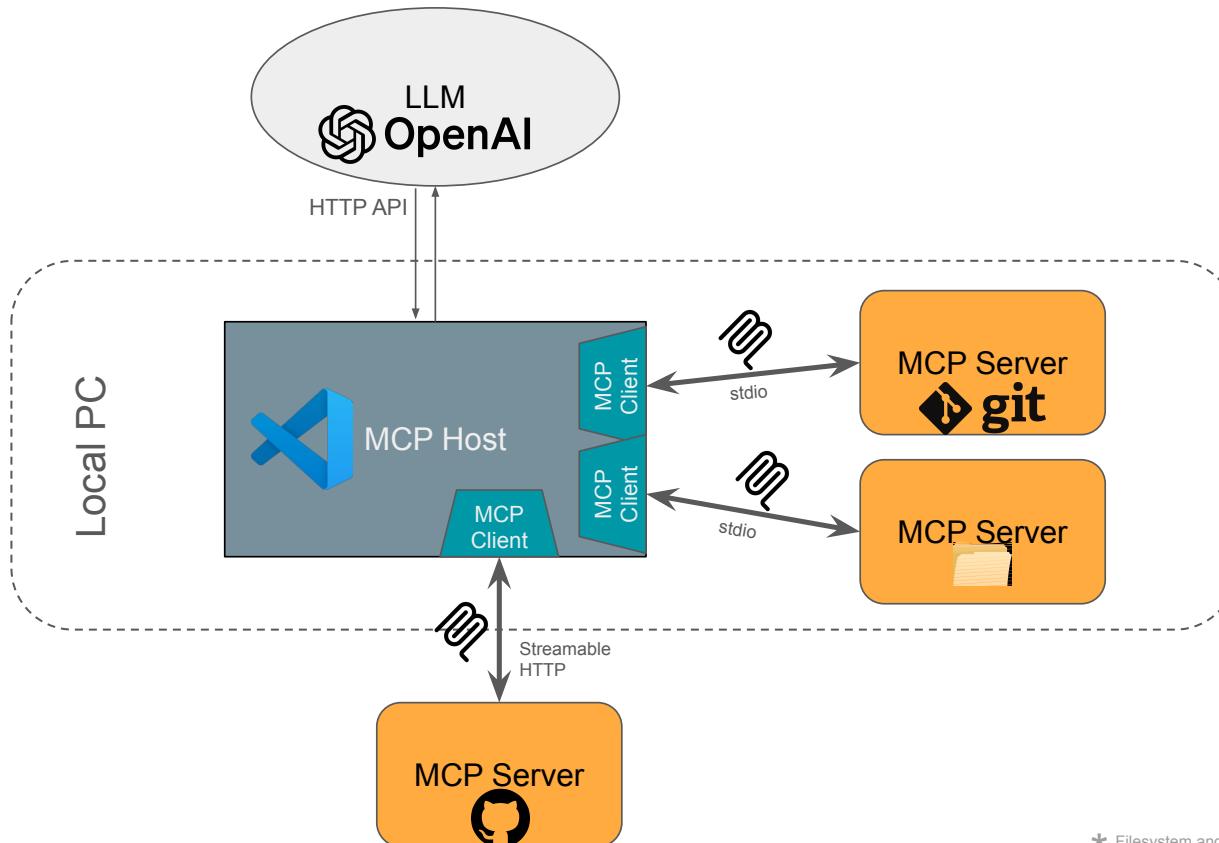

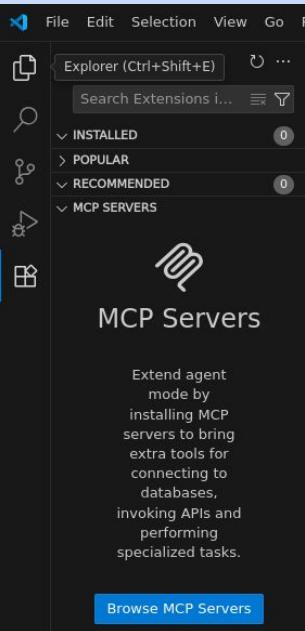

Think: API Specification tailored to AI-Applications

MCP as Communication Protocol

MCP Architecture

* Filesystem and git tools for LLMs are actually built-in in VS-Code.
We ignore this fact on this slide for the sake of this example.

MCP Features

Server Features

Client Features

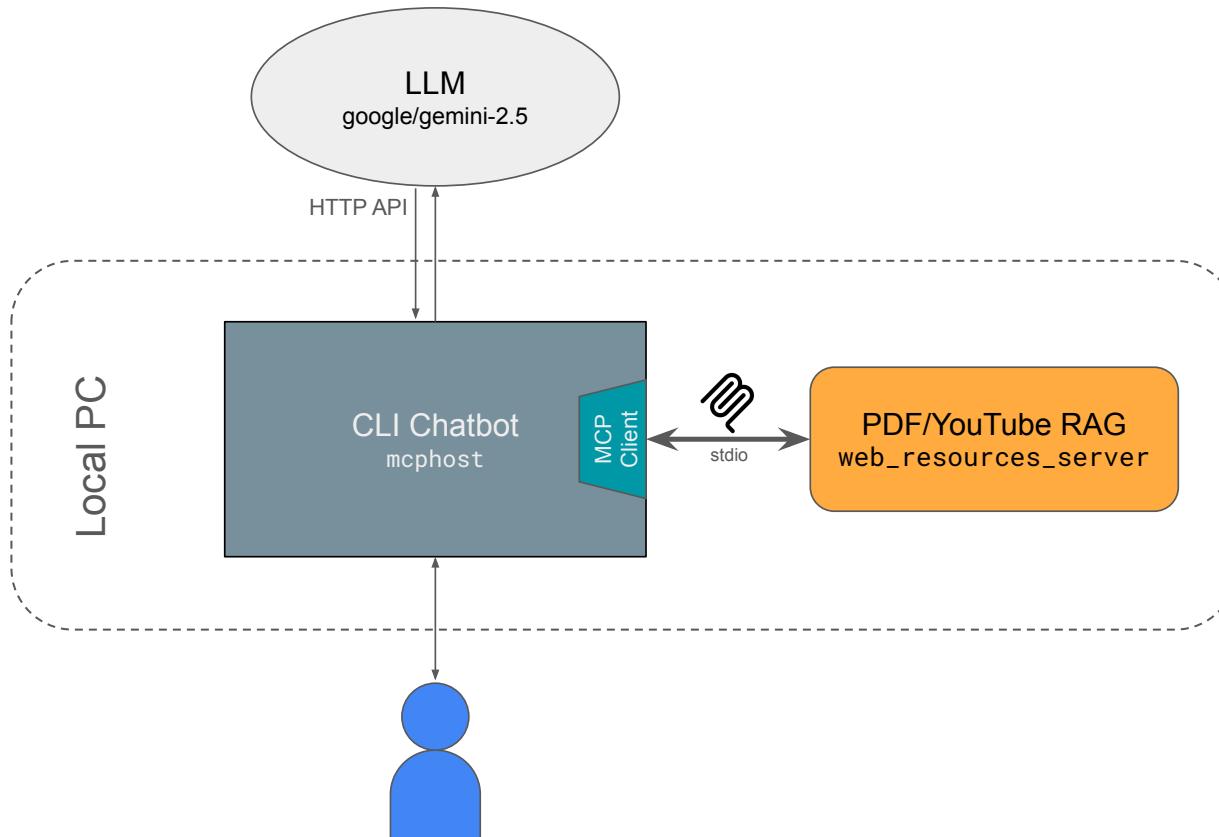

MCP Server: Tools

- Tools enable LLMs to interact with external systems
- *Model-controlled:*
LLM invokes tool calls and reacts to responses

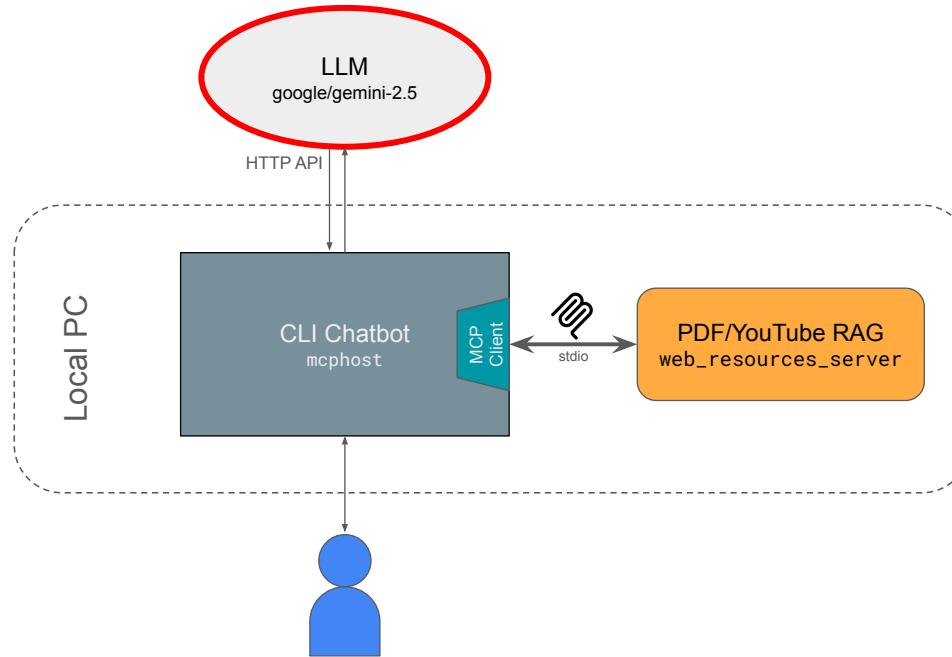

Minimal Example

MCP Server: Tools

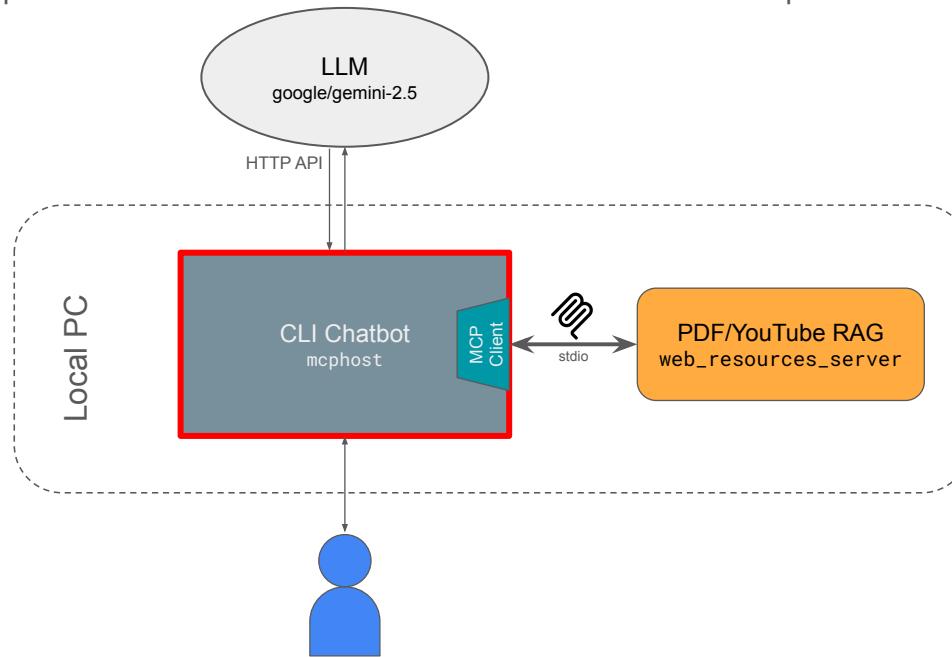

- Tools enable LLMs to interact with external systems
- *Model-controlled*:
LLM invokes tool calls and reacts to responses

MCP Server: Resources

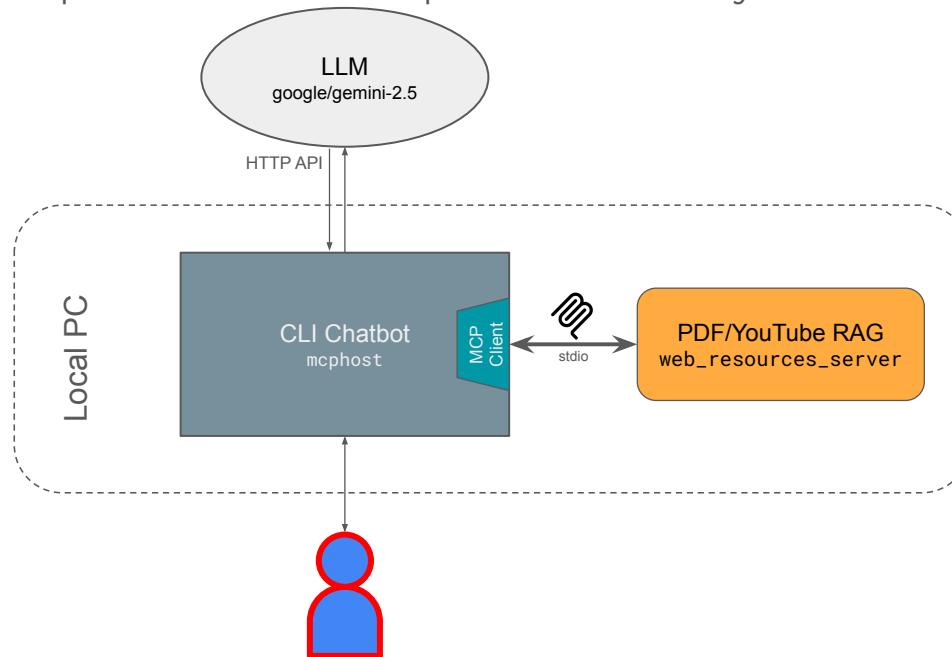

- Resources allow servers to share data with the MCP Host
- *Application-driven*:
MCP Host incorporates resources in workflows based on specific use-case

MCP Server: Prompts

- Prompts give users shortcuts through detailed templates tailored to the servers domain
- *User-controlled:*
Users invoke prompts to steer LLM responses effectively

MCP Server: Prompts

- Prompts give users shortcuts through detailed templates tailored to the servers domain
- *User-controlled:*
Users invoke prompts to steer LLM responses effectively

You are tasked with generating a short interesting transcript of a podcast interview between an interviewer and an expert on a specific topic.

<Task>

Your task is to create a transcript of a podcast interview that is engaging, informative, and aligned with the specified research topic and goals.

{expert_persona}

</Task>

<Instructions>

1. Analyze the input and check with the vector database for relevant information to understand the topic deeply (Use the retrieve_chunks and/or search_documents tools as needed)
2. Based on the retrieved info, if any, generate atleast 3 essential questions that, when answered, capture the main points and core meaning of the input.
3. When formulating your questions: a. Address the central theme (or themes if there are many) or argument (or arguments if many). b. Identify key supporting ideas c. Highlight important facts or evidence d. Reveal the author's purpose or perspective e. Explore any significant implications or conclusions.
4. Answer all of your generated questions one-by-one in detail, as an expert of the topic would.

</Instructions>

Important reminders:

- Stay in character as an interviewer and expert throughout the transcript.
- Ensure the transcript is coherent and flows naturally. So, instead of just listing questions and answers, weave them into a conversational format.
- Make the transcript engaging and informative.
- Avoid generic or vague statements; be specific and detailed.
- Ensure the content is accurate and factually correct.
- Use a conversational tone suitable for a podcast audience.
- Keep the transcript concise, ideally between 500 to 1000 words.

Here is your topic of research: {research_topic}

MCP Server Features

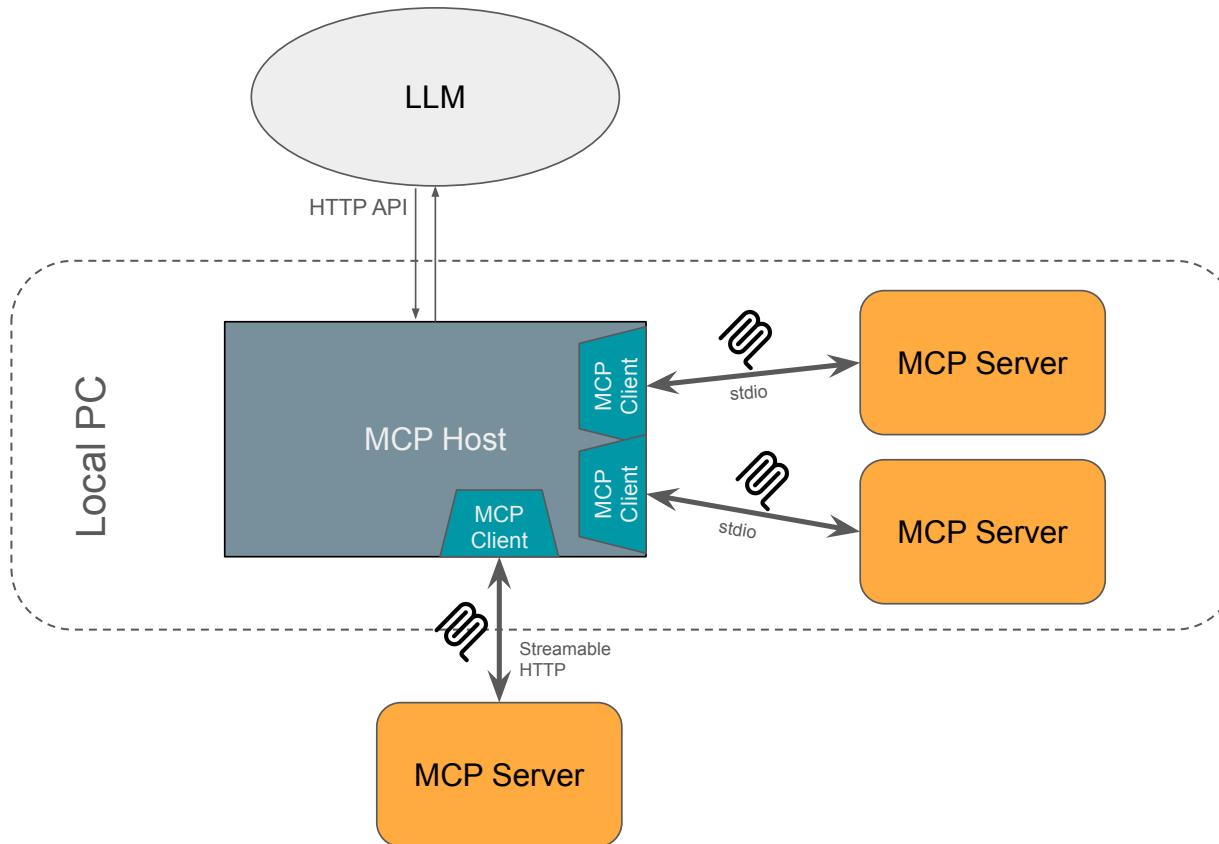

Feature	Controlled by...	Description
Tools	Model/LLM LLM decides what tools to call	Functions called by LLM <ul style="list-style-type: none">• API calls• File writes• Calculations• ...
Resources	Application Host/Agent/User decides what resources to view/add to context/...	Context injected by the Host <ul style="list-style-type: none">• File content• Git history• Config files• ...
Prompts	User User decides what prompts to expand	Templated Prompts Preconfigured fine-tune prompts tailored to domain of MCP-server

Questions so far?

Scaling up Orchestration Complexity

What & why – workflows

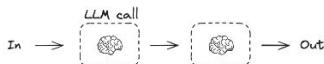

- **Workflows:**
 - LLMs and tools are orchestrated via pre-defined code paths.
 - Predefined rules control how a task is completed.
- **Agents** are DIFFERENT from **Workflows**!
 - Agents: systems where LLMs autonomously decide their processes and tool usage & how a task is completed
- Many ways to design workflows ⇒ many ways to design complex agentic systems.

Workflow architectures

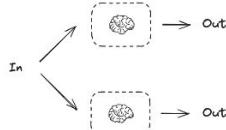

Workflows

Prompt Chaining

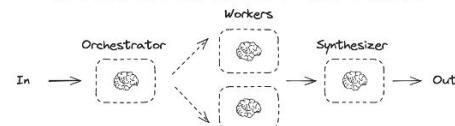

Parallelization

LLM is embedded in predefined code paths

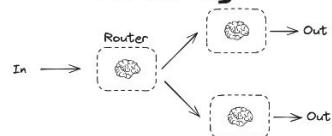

Orchestrator-Worker

Evaluator-optimizer

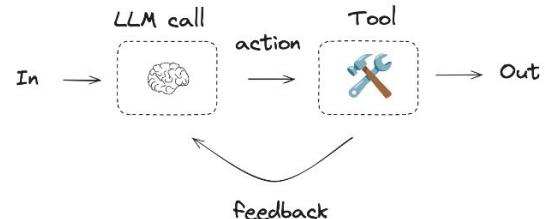

Routing

LLM directs control flow through predefined code paths

Agent

LLM directs its own actions based on environmental feedback

Send API

- Sometimes it's useful for different versions of the **State** to exist in parallel to speed up processing.
- It's also useful to be able to create them dynamically, depending on the current state.
- For that we need to be able to *send* custom inputs to any number of nodes (or instances of those nodes) in our graph.

```
def continue_to_jokes(state: OverallState):
    return [Send("generate_joke", {"subject": s}) for s in state['subjects']]

graph.add_conditional_edges("node_a", continue_to_jokes)
```

Configurables

- A **configurable** is used for passing in values to our invocation of the graph that are not altered during runtime.
- It's a dictionary found in `config["configurable"]`
- Examples:
 - Memory thread_id
 - Which LLM/provider to use
 - Limits to parallel executions and looping
 - Verbosity

State

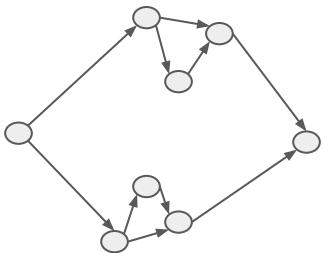

Typed Dictionary used for values that are altered during graph's execution.

`config["configurable"]`

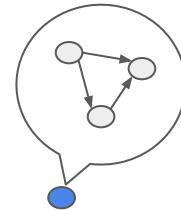

Dictionary used for passing in runtime arguments for the graph's execution.

SubGraph as Node

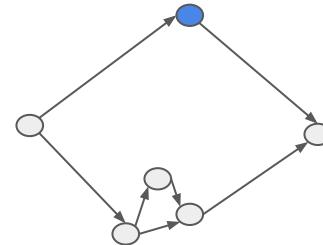

- When complexity & number of nodes increases, thinking in hierarchical levels can help.
- Instead of [A → B → C → P → Q → R] we can wrap the sub-graph C → ... → Q in a node too!
- Graph then becomes much simpler to operate.
- It also allows us to easily parallelize subgraph execution using **Send()**

Graph with multiple instances of a sub-graph

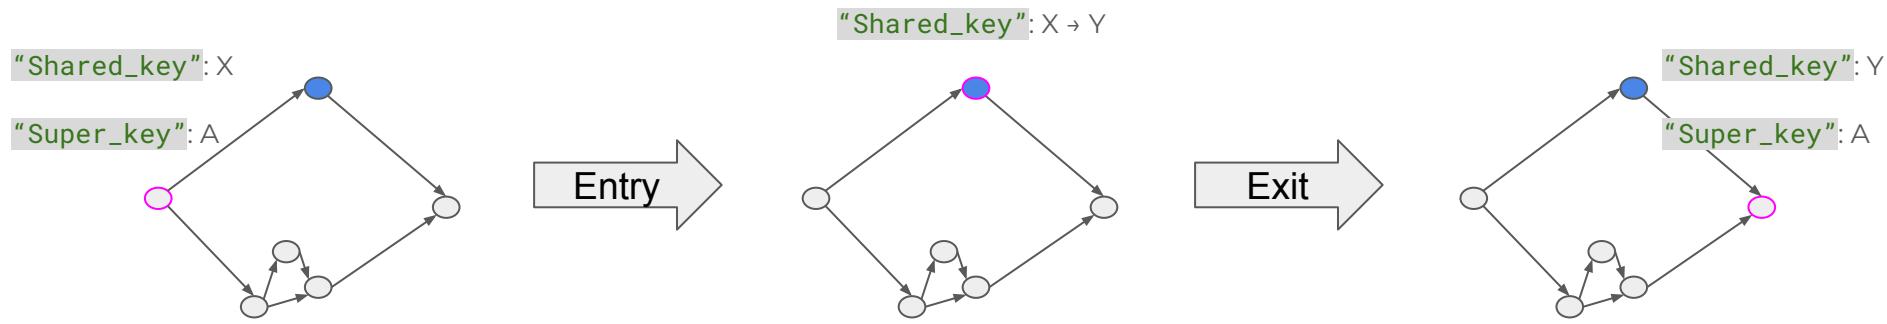

Wrap sub-graph as one node

Reduced complexity

SuperStates & SubStates

- (Super-)graphs and sub-graphs can have separate state schemas.
- Sub-graph's state is not persistent between calls!
- If those share a key called "**shared_key**":
 - **Entry:** Sub-graph receives the current value from super-graph.
 - **Exit:** Sub-graph's output is merged into super-graph using the super-graph's reducer.

Final example: Deep-Research

Tavily - Agent Web Search

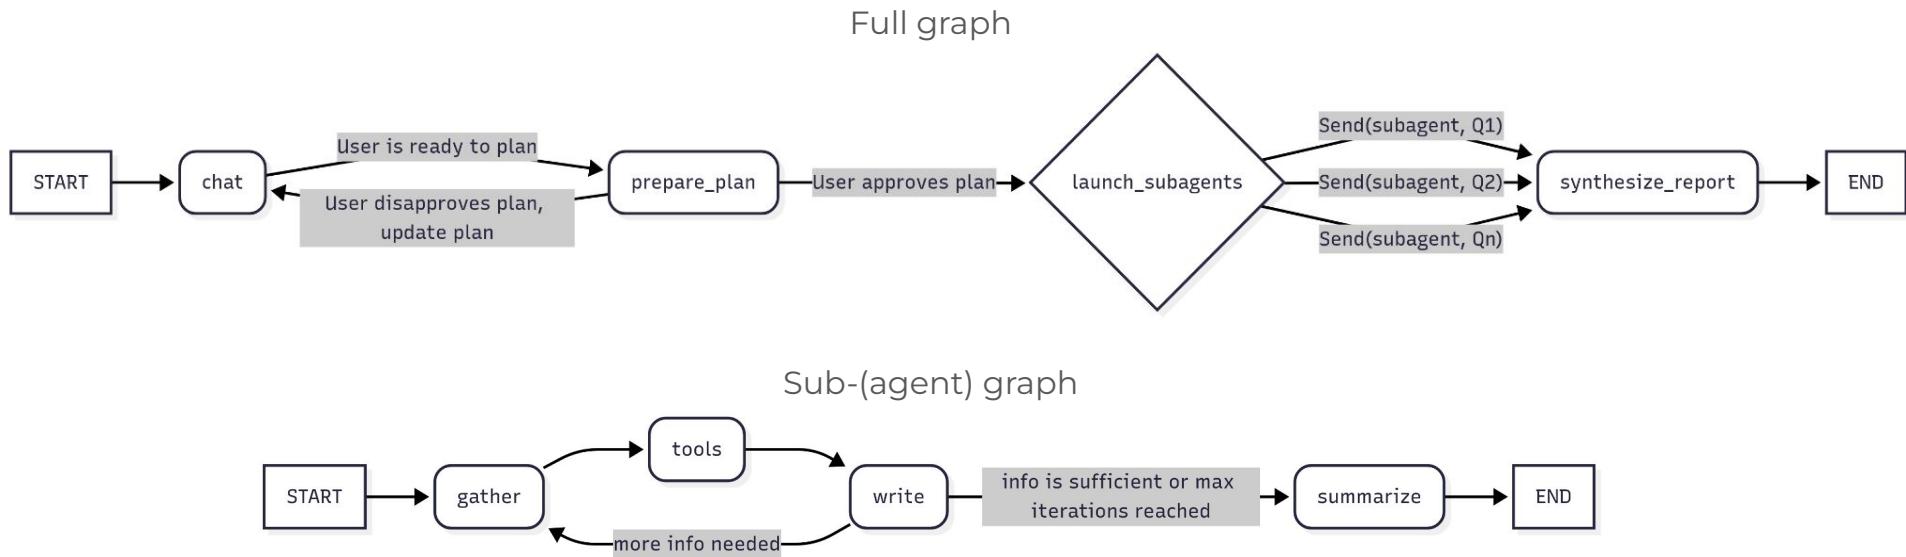

- Useful agent web-search API
- Not required if you want to use it, you can make an account with Github SSO and get free API credits.

<https://www.tavily.com/>

Example: deep research agent

- Given a research question, a Supervisor agent dynamically instantiate and instructs K parallel Sub-Agents that research sub-topics.
- After each Sub-Agent satisfactorily researches the sub-topic, a final report is written.

Questions?

Recap: what did we learn?

- **Basic syntax and concepts**
 - States
 - Nodes
 - Edges
- **Designing agentic systems**
 - Tools
 - Interruptions +Human-in-the-loop
 - Agent as a supervisor for parallel sub-graphs

Dive further!

- More (custom) design patterns
- Reflection for agents
- Prompt optimisation
- Deployment & request management
- Built-in LangGraph GUIs + system monitoring
- ... and so much

Mini-hackathon after the coffee break

- Take what you learnt to **build a cool agent**
- All ideas welcome, but **if you're looking for inspiration:**
 - Issue manager for your GitHub
 - Automated “related work” writer
 - Automated fairness/compliance summarizer for open-source LLMs
 - Mini research group simulation
 - ... **OR propose a completely new one!**
- [MCP Registry](#) (a curated list of MCP servers)

Enjoy your coffee!

Mini-hackathon
